## INTRODUCTION

The Rhode Island Childhood Lead Poisoning Prevention Program has a strategic plan to eliminate lead poisoning by 2010

([www.health.ri.gov/lead/databook](http://www.health.ri.gov/lead/databook)). The main objective of this plan is for each city and town to decrease the proportion of new cases of lead poisoning in children under six years of age to less than 5% without decreasing the availability of lead safe, affordable housing.

Over the past ten years, new cases of lead poisoning in Rhode Island have been concentrated in cities where, according to the 2000 Census, the child poverty rate is greater than 15%. These cities are designated as “core cities” and include Central Falls, Newport, Pawtucket, Providence, West Warwick, and Woonsocket. For this reason, we are presenting data specific to each of the core cities so that legislators, community leaders, and the public better understand the extent of the lead poisoning problem in these areas.

## ELIMINATING CHILDHOOD LEAD POISONING BY 2010

The Centers for Disease Control and Prevention (CDC) requires all state and local Childhood Lead Poisoning Prevention Programs, including the Rhode Island Program, to develop a strategic plan to eliminate childhood lead poisoning by 2010. As part of that plan, CDC encourages each state to develop a state-specific definition for elimination of lead poisoning based on local data. The elimination goal in Rhode Island is:

***“To decrease the proportion of new cases [incidence] of lead poisoning (defined as a blood lead level of 10 µg/dL or more) in children under six years of age to less than 5% in all Rhode Island communities without decreasing the availability of lead safe, affordable housing.”***

The strategy for elimination is two-fold: reduce incidence and ensure the availability of lead safe, affordable housing. Despite the fact that incidence has been decreasing throughout the state, we will not reach elimination without addressing the housing component.

In July 2004, the Rhode Island Childhood Lead Poisoning Prevention Program (RI CLPPP) created a Plan to achieve this goal called “Rhode Island’s Plan to Eliminate Childhood Lead Poisoning by 2010” [www.health.ri.gov/lead/databook](http://www.health.ri.gov/lead/databook). The Plan has three main objectives:

1. To support the implementation of the Lead Hazard Mitigation Law in Rhode Island
2. To formulate innovative primary prevention strategies to achieve elimination
3. To maintain and re-evaluate secondary prevention efforts

The Plan describes how progress on each objective can be measured using data in the RI CLPPP database, and, in some cases, data available to the Program from other state and local agencies. The Plan calls for an evaluation of the elimination goal using both of the following components together:

1. Incidence: The incidence of childhood lead poisoning is estimated for each city and town and calculated by dividing the number of new cases of lead poisoning (children with a blood lead level  $\geq 10$  µg/dL for the first time in their lives), by the total number of children screened, who have never had a blood lead level  $\geq 10$  µg/dL.
2. Lead safe, affordable housing: This measure is still being developed. Measuring the availability of lead safe, affordable housing is a challenge, both with respect to identifying lead safe units and determining how many are affordable. In the last few months, RI CLPPP has been working to develop a feasible way to assess the availability of lead safe, affordable housing. Efforts include:
  - a) Forming a RI CLPPP Advisory Committee workgroup to help develop a housing measure. The workgroup will contact the numerous local and state agencies that possess housing data and report back on the availability of these data and the formatting barriers that limit their utility.
  - b) Using the report and logic model developed by two students from the Harvard School of Public Health to design a measure to track the availability of lead safe, affordable housing.
  - c) Establishing stronger relationships with housing agencies, including the local Lead Hazard Reduction Programs, the Weatherization Program, the Housing Resources Commission, Rhode Island Housing, and the U.S. Environmental Protection Agency (EPA).
  - d) Promoting the use of RI CLPPP’s public data among lead poisoning prevention advocates. These data include public lists of properties, such as High Risk Premises, Properties with Multiple Poisonings, and Ongoing Violations, and are published on RI CLPPP’s web site as required by the Lead Hazard Mitigation Law. These public lists can be found on the web at [www.health.ri.gov/lead](http://www.health.ri.gov/lead).

## UNDERSTANDING THE LEAD DATA

In Rhode Island, health care providers are required by law to screen their patients between nine months and six years of age for lead poisoning annually. The screening process involves collecting a sample of blood from the child, either from a capillary (fingerstick) or a vein (venous test), and analyzing the blood to determine the amount of lead in the sample. Blood lead levels (BLL) are measured and reported as micrograms of lead per deciliter of blood ( $\mu\text{g}/\text{dL}$  or  $\text{mcg}/\text{dL}$ ).

Although the guidelines recommend that children begin to be screened at nine months of age, some children may be screened earlier if they are at high risk for lead poisoning. The data presented in this report are based on the results of all blood lead tests, both capillary and venous, performed on children from birth to six years of age in the state of Rhode Island.<sup>1</sup> For the incidence and prevalence analyses, each child is represented once per year in which he was screened.

For surveillance purposes in Rhode Island, any child under the age of six with a blood lead level  $\geq 10 \mu\text{g}/\text{dL}$  is considered lead poisoned. As the Centers for Disease Control and Prevention (CDC) states, it is not possible to select a single number to define lead poisoning for various intervention activities. According to guidelines from the CDC, community prevention activities, such as nutritional and educational campaigns, should be implemented at blood lead levels  $\geq 10 \mu\text{g}/\text{dL}$ , and individual prevention activities, such as case management and environmental investigations, should be implemented at blood lead levels  $\geq 15 \mu\text{g}/\text{dL}$ .<sup>2</sup>

---

<sup>1</sup> Given that calculations in this document are based on screening data rather than population data for all children under the age of six, the numbers presented here are estimates.

<sup>2</sup> Preventing Lead Poisoning in Young Children: A Statement by the Centers for Disease Control- October 1991. U.S. Department of Health and Human Services, Public Health Service, Centers for Disease Control, Atlanta, GA 30333.

## Occurrences of Lead Poisoning in Rhode Island are broken down into the following action levels

Action Level	Blood Lead Level (BLL)	Action
Elevated Blood Lead (EBL)	One BLL between 10-14 µg/dL	<p><b>Capillary:</b> Letter sent to Primary Care Provider recommending venous test to confirm the BLL*</p> <p><b>Venous:</b> Letter sent to family inviting them to request a home visit through the Family Outreach Program*</p>
Preventive	One BLL between 15-19 µg/dL	<p><b>Capillary:</b> Letter sent to Primary Care Provider recommending venous test to confirm the BLL</p> <p><b>Venous:</b> Family is referred to a lead center for an in-home lead education visit and some environmental intervention (i.e. temporary lead hazard control measures, window replacement)</p>
Significant	One Venous BLL $\geq 20$ µg/dL or Two BLLs (capillary or venous) $\geq 15$ µg/dL done 90-365 days apart**	Family is referred to a lead center for comprehensive case management and is offered an environmental inspection

\* In addition to the actions described, a letter is sent to families living in Providence ONLY informing them that they can contact the city of Providence for a free environmental inspection of their home.

\*\* Two blood lead levels (capillary or venous)  $\geq 15$  µg/dL may also be referred to as “persistent lead poisoning.”

In 1991, the Centers for Disease Control and Prevention (CDC) defined an elevated blood lead level (also referred to as “level of concern”) as a blood test result  $\geq 10$  µg/dL, and suggested that children with elevated blood lead levels be monitored and re-tested. Recent research suggests that blood lead levels lower than 10 µg/dL can have harmful health effects.<sup>3,4</sup>

In response to questions about whether to change the “level of concern,” CDC has prepared the following statement, which can be found on their website at [www.cdc.gov/lead/qanda.htm](http://www.cdc.gov/lead/qanda.htm):

“Recent studies suggest that adverse health effects exist in children at blood lead levels less than 10 µg/dL. In the past the CDC has lowered the level considered elevated in response to similar reports. However, at this time the reasons not to lower the level of concern are as follows:

- No effective clinical interventions are known to lower the blood lead levels for children with levels less than 10 µg/dL or to reduce the risk for adverse developmental effects.
- Children cannot be accurately classified as having blood lead levels above or below a value less than 10 µg/dL because of the inaccuracy inherent in laboratory testing.
- Finally, no evidence exists of a threshold below which adverse effects are not experienced. Thus, any decision to establish a new level of concern would be arbitrary and provide uncertain benefits.

These studies support making primary prevention of childhood lead poisoning a high priority for health, housing, and environmental agencies at the state, local, and federal levels.”

# COMPLIANCE WITH LEAD SCREENING GUIDELINES

All Rhode Island children between nine months and six years of age are required by law to be screened for lead poisoning annually. Compliance with these guidelines is assessed by measuring the proportion of children born in a given year (birth cohort) with at least one blood lead test by 18 months of age and the proportion of children born in a given year with at least two blood lead tests by 36 months of age.

## One Screening Test by 18 Months of Age

Screening children by 18 months of age is important to promptly identify children with elevated blood lead levels and offer intervention services. Rhode Island has one of the highest screening rates in the nation. Approximately 75% of children in Rhode Island are screened at least once by 18 months of age. This rate has been consistent between 1998 and 2001.\* The screening rates among children 18 months of age in Central Falls are slightly lower than the screening rates statewide.

## Two Screening Tests by 36 Months of Age

Compliance with the screening guidelines decreases as children get older. The statewide screening rate drops to approximately 52% when looking at the percent of children with two screening tests by 36 months of age. This rate has been fairly consistent between 1998 and 2001.\* The screening rates among children 36 months of age in Central Falls are slightly higher than the screening rates statewide.

A variety of outreach efforts have been made to achieve this high rate of screening, such as sending reminders to parents to have their children tested at the 12 month well-child visit and providing pediatric practices with lists of unscreened children in their practices between the ages of 22 and 24 months. In addition, many pediatric practices have access to KIDSNET, an electronic database containing preventive health information for all children born in the state since 1997. KIDSNET allows doctors to monitor lead screening rates in their practices.

Figure 1 demonstrates the need to focus screening efforts on children after 18 months of age.

\* Birth cohorts beyond 2001 are not included here because those children had not yet turned 36 months of age by the time this report was prepared.

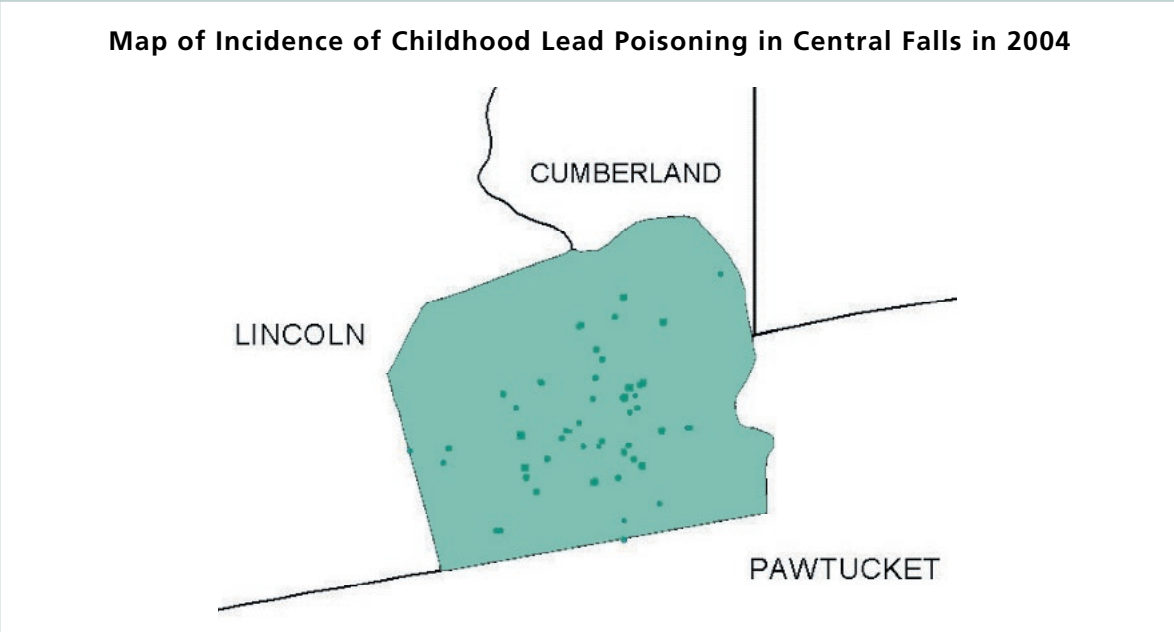

# INCIDENCE OF LEAD POISONING

The Department of Health tracks and reports the number of newly lead poisoned children. This is known as the incidence of lead poisoning. Incident cases include children with a blood lead level  $\geq 10 \mu\text{g/dL}$  who are less than six years of age and who have never had an elevated blood lead level in the past.

Over the past ten years, the proportion of new cases of lead poisoning among children in Central Falls has declined from 24.9% in 1995 to 7.7% in 2004. Although the incidence of lead poisoning has been declining steadily for the past ten years, there was an increase of 1.8% between 2003 and 2004. Seventy-seven children living in Central Falls were lead poisoned for the first time in 2004.\* In spite of the considerable decline in incidence over time, the increase in incidence for 2004 in Central Falls indicates that we must maintain our efforts to prevent childhood lead poisoning.

As seen in the map below, the cases of lead poisoning in Central Falls are distributed relatively evenly throughout the city.

\* 29 of the newly lead poisoned children were screened with a capillary test; 48 were screened with a venous test. As of July 1, 2004, the revised screening guidelines require that all capillary tests  $\geq 10 \mu\text{g/dL}$  be followed-up with a venous test.

## INCIDENCE OF LEAD POISONING BY AGE

The distribution of newly lead poisoned children by age in Central Falls in 2004 is similar to the statewide distribution. However, in Central Falls, 7.8% of lead poisoned children are under age one, compared to 5.5% of lead poisoned children statewide. This suggests either that children in Central Falls are being lead poisoned earlier in life than in other cities and towns across Rhode Island, or that residents of Central Falls screen their children for lead at a younger age.

## INCIDENCE OF LEAD POISONING BY BLOOD LEAD LEVEL

The distribution of newly lead poisoned children by blood lead level in Central Falls in 2004 follows a trend comparable to the statewide distribution. The percentage of children with blood lead levels of 15-19  $\mu\text{g}/\text{dL}$  is slightly higher in Central Falls, while the percentages of children with blood lead levels in the 10-14  $\mu\text{g}/\text{dL}$ , 20-24  $\mu\text{g}/\text{dL}$ , and 25+  $\mu\text{g}/\text{dL}$  ranges are slightly lower in Central Falls compared to the statewide rate.

The greatest difference between Central Falls and the state rate can be seen in the 15-19  $\mu\text{g}/\text{dL}$  category. In Central Falls in 2004, 26% of newly lead poisoned children had blood lead levels between 15-19  $\mu\text{g}/\text{dL}$ , compared to 18.1% of newly lead poisoned children statewide. This indicates that there is a higher proportion of cases with blood lead levels between 15-19  $\mu\text{g}/\text{dL}$  in Central Falls than other cities and towns throughout the state.

## PREVALENCE OF LEAD POISONING

The Rhode Island Department of Health calculates the prevalence of lead poisoning annually. The prevalence rates presented here show the proportion of children with a blood lead level  $\geq 10$   $\mu\text{g}/\text{dL}$  in a given year, and include children who had been lead poisoned in the past.

Figure 5: Percent of Lead Poisoning in Central Falls and Statewide 1995-2004

Over the past ten years, the prevalence of lead poisoning among children in Central Falls has declined from 32.3% in 1995 to 9.4% in 2004. This decline is consistent with the statewide trend over the last ten years.

Although the prevalence of lead poisoning has decreased over time, a total of 106 children living in Central Falls had lead poisoning in 2004, and the trend of declining rates did not extend to 2004.

## PREVALENCE OF LEAD POISONING BY AGE

Overall, the distribution of children with lead poisoning by age in Central Falls in 2004 is similar to the statewide distribution, with the majority of lead poisoning affecting children between 24 and 47 months of age in Central Falls.

Figure 6: Distribution of Lead Poisoned Children by Age in Central Falls and Statewide 2004

## PREVALENCE OF LEAD POISONING BY BLOOD LEAD LEVEL

The distribution of lead poisoning by blood lead level in Central Falls in 2004 generally follows the statewide distribution. Blood lead levels of 10-14  $\mu\text{g/dL}$  and 20-24  $\mu\text{g/dL}$  are slightly lower in Central Falls compared to statewide.

Almost two-thirds of lead poisoned children in Central Falls, as well as throughout the state, have blood lead levels between 10-14  $\mu\text{g/dL}$ . The percentage of children with blood lead levels between 15-19  $\mu\text{g/dL}$ , however, is considerably higher in Central Falls (26.4%) compared to statewide levels (19.9%). This indicates that lead poisoned children in Central Falls have a higher proportion of lead levels between 15-19  $\mu\text{g/dL}$  than lead poisoned children throughout the state.

## ENVIRONMENTAL INSPECTIONS OFFERED

In Rhode Island, comprehensive environmental inspections are offered to families of children who have an environmental intervention blood lead level (EIBLL)\*. Families are offered an environmental inspection at no cost. The landlord's permission is neither required nor sought for the inspection to occur.

Although inspections are offered to all children with environmental intervention blood lead levels, the inspections may not be performed if the family cannot be located or they do not respond to letters or phone calls. In addition, inspections are not performed if a child moves or if the family refuses the inspection.

In 2004, inspections were offered to nine families in Central Falls. Inspections were performed in eight homes. One family did not receive an inspection because the child moved. In all inspections performed, lead hazards were found.

For more detailed information about environmental inspections offered between 2000 and 2004, see the table below:

	2000	2001	2002	2003	2004
<b>Inspections Offered</b>	<b>23</b>	<b>16</b>	<b>11</b>	<b>9</b>	<b>9</b>
Child Moved	1	2	0	1	1
No Response to Letters and Calls	0	1	0	1	0
Inspection Refused	1	4	1	3	0
Pending Inspection	0	0	0	0	0
<b>Inspections Performed</b>	<b>21</b>	<b>9</b>	<b>10</b>	<b>4</b>	<b>8</b>

\*For the purposes of environmental inspections, EIBLL is synonymous with significant lead poisoning.  
Report run 4/04/05

## STATUS OF ENVIRONMENTAL INSPECTIONS

An environmental case is opened for each child with an environmental intervention blood lead level who receives an inspection. Once the case is opened, the Department of Health works with the property owner until the entire property, including the interior, exterior, and soil, are abated and free of lead hazards. In some instances, cases are closed before abatement is complete. This can occur if the parent of the child is the owner of the property or if the property is no longer regulated, such as illegal apartments that have been dismantled, properties that have been converted to commercial use, or properties that have been razed.

Of the eight environmental cases that were opened in Central Falls in 2004, two have been completely abated. Two properties have achieved interior lead safe status and are awaiting exterior abatement, and the remaining four are in various stages of the abatement process.

For a breakdown of the status of cases opened in 2000-2004, see the table below.

	2000	2001	2002	2003	2004
<b>Closed Cases</b>	<b>17</b>	<b>8</b>	<b>10</b>	<b>4</b>	<b>2</b>
No Lead Hazards Found	0	0	1	0	0
No Longer Regulated	0	0	0	0	0
Parent is Owner of Property	1	0	1	0	0
Closed Pending Soil	3	0	0	0	0
Abatement Complete	13	8	8	4	2
<b>Ongoing Cases</b>	<b>4</b>	<b>1</b>	<b>0</b>	<b>0</b>	<b>6</b>
Pending Soil	1	1	0	0	0
Exterior Abated, Interior pending	0	0	0	0	0
Interior abated, Exterior pending	1	0	0	0	2
Enrolled or Enrolling in a HUD program, Awaiting Abatement	0	0	0	0	0
Various Stages of Abatement	2	0	0	0	4
<b>Total Cases</b>	<b>21</b>	<b>9</b>	<b>10</b>	<b>4</b>	<b>8</b>

## DATA TABLES

Table 1. Percent of Children in Central Falls in Compliance with Screening Guidelines 1998-2001

Year Born	Total Number of Children Born	Number of Children Screened at Least Once by 18 Months of Age	Number of Children Screened at Least Twice by 36 Months of Age
1998	240	172 (71.7%)	133 (55.4%)
1999	195	132 (67.7%)	99 (50.8%)
2000	224	170 (75.9%)	125 (55.8%)
2001	355	253 (71.3%)	195 (54.9%)

Age	Number of Children with BLL $\geq 10$ $\mu\text{g/dL}$	Percent of Children with BLL $\geq 10$ $\mu\text{g/dL}$
<12 months	64	3.8%
12-23 months	469	27.8%
24-35 months	445	26.4%
36-47 months	332	19.7%
48-59 months	227	13.5%
60-72 months	148	8.8%
Total	1,685	100%

Table 7A. Prevalence of Lead Poisoning by Blood Lead Level in Central Falls 2004

Blood Lead Level	Number of Children with Elevated Blood Lead Levels	Percent of Children with Elevated Blood Lead Levels
10-14 $\mu\text{g/dL}$	63	59.4%
15-19 $\mu\text{g/dL}$	28	26.4%
20-24 $\mu\text{g/dL}$	6	5.7%
25+ $\mu\text{g/dL}$	9	8.5%
Total	106	100%

Table 7B. Prevalence of Lead Poisoning by Blood Lead Level Statewide 2004

Blood Lead Level	Number of Children with Elevated Blood Lead Levels	Percent of Children with Elevated Blood Lead Levels
10-14 $\mu\text{g/dL}$	1,108	65.8%
15-19 $\mu\text{g/dL}$	336	19.9%
20-24 $\mu\text{g/dL}$	116	6.9%
25+ $\mu\text{g/dL}$	125	7.4%
Total	1,685	100%

## GLOSSARY

**BLL:** Blood lead level.

**EBL:** Elevated blood lead. A single blood lead level between 10-14 µg/dL.

**EIBLL:** Environmental intervention blood lead level. Synonymous with Significant Lead Poisoning.

**Incidence:** The proportion of new cases of a disease that develops during a specified time period among the population at risk for developing the disease. The population at risk for lead poisoning is defined as Rhode Island children under the age of six who have been screened for lead in a given year, and who have never had an elevated blood lead level.

**Lead Hazard Mitigation Law:** Legislation passed by the Rhode Island General Assembly in June 2002 that takes effect on November 1, 2005. The Law modified the Lead Poisoning Prevention Act and established standards for the maintenance of pre-1978 rental property in Rhode Island.

**NOV:** Notice of violation. A notice sent to a property owner after an environmental lead inspection or lead assessment has been performed and environmental lead hazards have been identified. The notice informs the property owner that significant environmental lead hazards exist on his property and requires the owner to abate all identified hazards in accordance with Rhode Island Department of Health regulations.

**Persistent Lead Poisoning:** A case of a child under age six with two blood lead tests (capillary or venous) done between 90 and 365 days apart that are  $\geq 15$  µg/dL.

**Prevalence:** Proportion of people in a population who have a given disease at a specific point in time.

**Preventive Lead Poisoning:** A case of a child under age six with a single blood lead level between 15 and 19 µg/dL for the first time.

**RI CLPPP:** The Rhode Island Childhood Lead Poisoning Prevention Program.

**Screening:** Mandatory test that involves collecting a blood sample from a child under the age of six, either through a fingerstick or a venipuncture. The sample is then analyzed to determine the amount of lead in the child's blood.

**Significant Lead Poisoning:** A venous blood lead level  $\geq 20$  µg/dL in a child under six years of age, or two blood lead tests (capillary or venous) from a child under six years of age, done between 90 and 365 days apart, with a blood lead level  $\geq 15$  µg/dL. Synonymous with EIBLL.

**µg/dL:** Micrograms per deciliter of whole blood; the measurement used to estimate the amount of lead in a sample of blood. This measure is sometimes represented as mcg/dL.
